Abstract

In this study an effort has been made for the plasma ion nitriding (PIN) of Inconel 600 and 601 alloys at low temperatures. After plasma ion nitriding and microstructural study, growth kinetics of nitrided layer formation and wear properties were investigated by various characterization techniques such as scanning electron microscope (SEM), X-ray diffraction (XRD) analysis, micro-hardness measurement and wear test by pin on disk technique. It was found that surface micro-hardness increases after the PIN process. A mixed peak of epsilon (ɛ) and fcc (γ) phase was detected for all temperature range (350 to 450 °C), while the chromium nitride (CrN) phase was detected at elevated temperature range ~450 °C in Inconel 601 alloy. The calculated values of the diffusion coefficient and activation energy for the diffusion of nitrogen are in accordance with the literature. Volume loss and wear rate of the plasma nitrided samples decreases, but it increases as PIN process temperature increases.

Keywords: Micro-hardness; X-ray diffraction; Wear test; Diffusion coefficient; Plasma nitriding.

1. Introduction

Ni-base alloys are widely used material for various applications such as; chemical processing plants, gas turbines, heat exchanger, and nuclear industries due to excellent corrosion resistance and resistance to heat properties. Inconel 600 and 601 alloys have excellent properties but show poor wear resistance, low surface hardness, and a high coefficient of friction [1]. These disadvantages can be improved by surface modification. Many surface modification processes such as diffusion processes (nitriding, carburizing, boriding etc.) and coating processes (CVD, PVD, PECVD etc.) have been tried by various researchers [2–7]. Pulsed DC plasma ion nitriding is a diffusion process and the most promising technique to improve the surface properties of Ni and Fe based alloys, because it has excellent dimensional control, low distortion, environment friendliness and complete process is
auto control [8]. It is a thermochemical process in which nitrogen is introduced into the metal surface as an interstitial solid solution [8].

Plasma nitriding of pure iron (Fe) and Fe based alloys has been thoroughly explained by various researchers [9–14] but very little information on nickel-based alloys is available in the literature. Williamson et al. [15] studied that, when Ni-Fe alloys are exposed to low energy, high current density nitrogen ion beam the nitriding affinity reduced with the increasing of Ni concentration. Pedraza et al. [16] reported that Ni and Ni-Cr based alloys form thinner nitrided layer compared to Fe based alloys when these were nitrided under the ion implantation technique. Aw et al. [17] studied the plasma nitriding behavior of Inconel 718 alloy at temperature range 550 to 750 °C for 16h treatment time. In this study it was found that the time and temperature were not effective to increase the nitrided layer thickness. Mindivan et al. [18] studied the wear performance of Inconel 600 by different nitriding processes, it was concluded that wear rate is lower for the pulsed plasma nitrided samples, but the nitriding processes did not significantly affect the surface hardness of such alloy. Aw et al. [19] reported the friction and wear behavior of plasma nitrided Inconel 718 alloy and demonstrated that the hard nitrided layer reduces the friction coefficient of the material. It was also concluded that the layer was prone to delimitation under contact motion resulting in the higher wear rate, i.e. a thicker nitrided layer was required to achieve improved tribological properties. Sudha et al. [20] studied the nitriding kinetics of Inconel 600 alloy, it was found that surface hardness increased from 200 to 1260 VHN after plasma nitriding at 600 °C for 24 h. The calculated value of activation energy for the diffusion of nitrogen was obtained as 0.65 eV. Sun [21] studied the layer growth kinetics during plasma nitriding of Inconel 600 alloy, it was concluded that the growth of the nitrided layer with temperature deviates from conventional diffusion law. It was also concluded that the nitrided layer follows two linear regimes, in a fast-growth regime the growth of the nitrided layer was governed by nitrogen diffusion in the layer. On the other hand in slow-growth regime nitrogen diffusion in the developed external scale governs the kinetics of nitrided layer growth. Some other studies on nitriding behavior of Ni-based alloys and Ni–Cr based composites under various experimental conditions have been reported by various workers [1, 22-28].

The existing information available in the literature was insufficient to understand the behavior of nitrided layer growth and wear properties at a low- temperature range. Therefore, the present work was focused to investigate the properties of Inconel 600 and 601 alloys at a lower temperature range ~350 - 450 °C after pulsed dc plasma ion nitriding. All the experiments were performed in Nitrogen (N₂) and Hydrogen (H₂) gas environment at the
ratio of N₂-H₂ (50-50) % at three different temperatures (350, 400, and 450 °C). After plasma nitriding, samples were characterized by various characterization techniques such as; scanning electron microscope (SEM), X-ray diffraction (XRD) analysis, micro-hardness measurement, and wear test by pin on disk method.

2. Sample Details and Preparation

Samples used for assessment were commercially available Inconel 600 and 601 alloys. The chemical compositions of these standard Inconel alloys are given in Table 1. Circular disc-shaped samples of two sizes: 15mm diameter x 20mm thickness prepared for SEM, XRD analysis and hardness measurement, and 10mm diameter x 10mm thickness sample prepared for wear testing. Initially, samples were polished with SiC emery papers of 240, 320, 400, 600, 800 grit size followed by a diamond paste of 1 μm grain size and alumina paste of 0.05 μm grain size. After polishing, the samples were washed with acetone for removal of dust/oil contamination from the surface and finally dried.

3. Plasma Nitriding Experimental Set-up

The schematic diagram of the experimental set-up for plasma ion nitriding has been shown in Figure 1. The main components of the experimental setup are; vacuum pump, gas cylinders, mass flow controllers (MFC), pulsed dc power supply, and thermocouple.

![Figure-1: Plasma nitriding experimental setup.](image-url)

Initially the chamber was evacuated up to the base pressure of ~5x10⁻³ mbar with the help of a rotary pump. After that Argon (Ar) and Hydrogen (H₂) gases were introduced into the chamber having a volume ratio of 50% Ar and 50% H₂ to maintain a gas pressure of 1 mbar which was measured by an absolute gauge. At this gas pressure,
initially a glow discharge plasma was ignited between the chamber wall as anode and substrate table as a cathode by applying pulsed dc voltage of ~400 Volts at ~30 kHz frequency. This Ar-H₂ discharge was utilized to remove the oxides and contaminants from the sample surface. After an hour, N₂-H₂ gases were introduced into the chamber in a volume ratio of 50% N₂ and 50% H₂ through mass flow controllers (MFC). A typical working gas pressure of ~4 mbar was maintained for carrying out the plasma nitriding process. A thermocouple was used to measure the sample temperature. The typical plasma nitriding operating parameters are given in Table 2.

4. Results and Discussion:

4.1. Micro-hardness measurement and analysis of surface morphology

Figure 2 shows the variation in surface micro-hardness with plasma nitriding process temperatures. The surface micro-hardness was observed to increase as process temperature increases. Initially, it is observed that the surface micro-hardness increases slowly up to the process temperature of 400 °C, while beyond this temperature range the surface micro-hardness increases rapidly in both the alloys. The maximum surface micro-hardness ~306 HV₀.₀₂₅ and ~330 HV₀.₀₂₅ were observed in Inconel 600 and 601 alloys, respectively. The increments in the surface hardness value after plasma nitriding from its initial surface hardness value (200-220 HV) were due to the formation of nitride phase during plasma nitriding at the surface.

![Figure 2: Variation of surface micro-hardness with plasma nitriding temperature.](image)

Sudha et al. [20] observed ~900 VHN surface micro-hardness in Inconel 600 alloy after nitriding at temperature 450 °C for 24 hours. It was also observed that surface hardness remain the same till 500 °C, beyond which it increased further with increasing temperature. Mindivan et al. [18] observed very slight changes in surface hardness when Inconel 600 alloy was plasma nitried at 520 °C for 12 hours. Figures 3 and 4 show the surface
morphology images of Inconel 600 and 601 alloys, before and after plasma nitriding at different process temperatures.

![morphology images](image1)

**Figure 3:** SEM surface morphology of Inconel 600 alloy (a) untreated sample. (b) plasma nitrided at 350 °C. (c) plasma nitrided at 400 °C. (d) plasma nitrided at 450 °C.

![morphology images](image2)

**Figure 4:** SEM surface morphology of Inconel 601 alloy (a) untreated sample. (b) plasma nitrided at 350 °C. (c) plasma nitrided at 400 °C. (d) plasma nitrided at 450 °C.

The average crystallite size of 5-9 nanometers was roughly calculated using the Scherrer formula [29] after plasma nitriding. In this calculation, peak broadening due to microstrains and instrumental broadening was not taken into consideration. It was observed from surface morphology images, the crystallite size increased as process temperature increased. Sudha et al. [20] calculated CrN crystallite size around 10nm after plasma nitriding for 24 h at 600 °C.

### 4.2. Identification of Phase composition in the nitrided layer

The results of X-ray diffraction analysis of Inconel 600 and Inconel 601 are shown in Figures 5 and 6. The untreated sample shows only the fcc (γ) phase corresponding to the Ni-Fe-Cr based matrix. After plasma nitriding an additional peak appeared at a position of 2θ (37.5°) which was identified as chromium nitride CrN phase in (111) plane. This CrN peak was observed only in the samples of Inconel 601 alloys which were plasma nitrided at...
450 °C. A mix peak of epsilon (ε) phase with fcc (γ) phase of (111) and (200) planes at the 2θ position of $41.62^\circ$, $43.28^\circ$, and $51.14^\circ$ were observed in all the plasma nitrided samples for all temperatures (350-450 °C). Sun [21] suggested that this mix peak may be resulted due to the formation of a thermodynamically unstable compound of ε-Ni$_3$N or (Ni, Cr, Fe, Mn)$_3$N$_{1-x}$ in the nitrided layer. It has been known that ε-Ni$_3$N is unstable under normal pressure and formed only at high nitrogen potentials [30].

![Figure 5: Comparison of the XRD pattern of Inconel 600 alloy before and after plasma nitriding.](image)

The characteristic of mixed peak formation during plasma nitriding was not observed in the study by Sudha et al. [20] and Mindivan et al. [18] for Inconel 600 alloy. The observed γ peaks were found to be asymmetric and broad.
in the plasma nitrided samples as compared to untreated samples. The peak broadening in the plasma nitrided samples were related to the development of stress in the sample matrix due to the diffusion of nitrogen.

### 4.3. Growth Kinetics of nitrided layer

Figures 7 and 8 show the cross-sectional micrographs of the plasma nitrided samples of Inconel 600 and 601 alloys obtained from a scanning electron microscope. The obtained micrograph shows the variation in the thickness of the nitrided layer with nitriding temperatures 350, 400 and 450 °C.

![Figure 7: SEM image of plasma nitrided layer of Inconel 600](image-url)

Figure 7: SEM image of plasma nitrided layer of Inconel 600 (a) plasma nitrided at 350 °C. (b) plasma nitrided at 400 °C. (c) plasma nitrided at 450 °C.

![Figure 8: SEM image of plasma nitrided layer of Inconel 601](image-url)

Figure 8: SEM image of plasma nitrided layer of Inconel 601 (a) plasma nitrided at 350 °C. (b) plasma nitrided at 400 °C. (c) plasma nitrided at 450 °C.

It was observed that the thickness of the nitrided layer increases in both the alloys as plasma nitriding process temperature increases. The maximum thickness of the nitrided layer ~3.70 μm and ~3.15 μm were observed in Inconel 600 and 601 alloys respectively. It was also observed that at 450 °C nitrided layer is divided into two sub-layers. The existence of the formation of a double layer structure in the nitriding of Ni-Cr alloys was reported in the literature [23, 31]. Sun [21] observed a ~7μm thick nitride layer for 5h nitriding and ~11μm thick nitride layer for 12h nitriding at 450 °C. It was also observed that the further increment in the nitriding temperature led to a
reduction in nitrided layer thickness. The temperature of 500-600 °C did not affect the layer thickness. Sudha et al. [20] observed a ~14μm thick nitride layer for nitriding at a temperature of 600 °C for 24h. In this study it was also observed that the layer thickness increased with increasing time for all nitriding temperatures 450-600 °C, but for longer treatment time increase in layer thickness was steeper than for shorter treatment time. Mindivan et al. [18] observed a 7 μm thick nitride layer for 12h nitriding at 520 °C.

Further, to understand the influence of plasma nitriding process parameters, the thickness of the nitrided layer was plotted as a function of plasma nitriding process temperature, as shown in Figure 9. Thickness was taken as the total nitrided layer (addition of sub-layers in case of the plasma of the samples nitrided at 450 °C).

![Figure 9: Variation in the total thickness of the plasma nitrided layer of Inconel 600 and 601 alloys with different plasma nitriding temperatures.](image)

Figure 9 shows that the thickness of the nitrided layer increases linearly with increasing plasma nitriding process temperature. As per the theory of diffusion in solids, the thickness of the nitrided layer 'X' is related to the nitriding time 't' through the following relation written as in equation (1) [32].

\[ X = \sqrt{D_n \cdot t} \]  

(1)

Here; '\( D_n \)' is the diffusion coefficient of nitrogen, which was related to the activation energy 'Q' and the pre-exponential term 'D_0' by a relation written as in equation (2) [32].

\[ D_n = D_0 \exp\left(-\frac{Q}{RT}\right) \]  

(2)

Or

\[ \ln \left(D_n\right) = \ln \left(D_0\right) - \frac{Q}{RT} \]  

(3)
Here; ‘\(D_0\)’ is the pre-exponential term and ‘\(Q\)’ is the activation energy, ‘\(R\)’ is the gas constant \(8.62 \times 10^{-5} \text{eV/atom-K}\), and ‘\(T\)’ is the absolute temperature. Using the measured values of nitrided layer thickness from SEM images for nitriding time duration 4h, values of diffusion coefficient ‘\(D_n\)’ were calculated by Equation (1), within the temperature range of 350 °C-450 °C. The value of \(D_n\) varies from \(2.5 \times 10^{-16} \text{m}^2/\text{s}\) to \(9.5 \times 10^{-16} \text{m}^2/\text{s}\) and \(7.2 \times 10^{-17} \text{m}^2/\text{s}\) to \(6.8 \times 10^{-16} \text{m}^2/\text{s}\) for Inconel 600 and 601 alloys respectively. Using Equation (3) \(\ln(D_n)\) Vs reciprocal of temperature (1/T) were plotted in figure 10.

**Figure 10:** Arrhenius plot of logarithmic of diffusion coefficient vs reciprocal of temperature (a) for 600 alloy and (b) for 601 alloy.

From this figure the values for activation energy ‘\(Q\)’ were calculated ~1.21 eV and ~1.24 eV for Inconel 600 and 601 alloys. Sudha et al. [20] reported that the value of activation energy was 0.65 eV for Inconel 600 alloy. Leroy et al. [23] obtained the value of diffusion coefficient of nitrogen \(~10^{-15} \text{m}^2/\text{s}\) and activation energy ~1.1 eV at 400 °C in Inconel 690 alloy. Matsuda et al. [33] reported the diffusion coefficient of nitrogen \(~8 \times 10^{-16} \text{m}^2/\text{s}\) and activation energy ~0.43 eV at 650 °C in Ni-20 wt.% Cr-2 wt.% Ti alloy. In another study made by Kodentsov et al. [34] reported values of diffusion coefficient of nitrogen ~1.8 \times 10^{-16} \text{m}^2/\text{s}\) and activation energy ~1.5 eV at 600 °C in Ni-5 at.% Cr alloy. On the other hand the similar calculated values of activation energy for the diffusion of nitrogen are presented by Sun [35] for the plasma carburizing kinetics of AISI 316L and AISI 304L stainless steels and Menthe and Rie [36] for the plasma nitriding of AISI 304L steel. It is to be noted that all the nickel
alloys and steels having high Cr and Ni contents, which explains the similarity of the activation energy values. The higher value of activation energy and the linear behavior of plasma nitriding thickness as a function of the square root of treatment time indicate that the whole process is controlled by the diffusion of the nitrogen atom in the layer.

4.4. Wear analysis of Plasma nitried samples

Wear test was performed on these alloys by the pin on disk method to analyze the wear properties. This test was performed in the dry condition with a 10N applied load. After the wear test mass loss was measured using three digits balancing machine. Using the values of mass loss, volume loss was calculated by using the well-known relation between mass, density, and volume. The calculated values of volume loss for both the alloys have reported in Table 3. It is evident that, the volume loss decreases after plasma nitriding. The minimum volume loss ~2.12 x 10^{-3} \text{cm}^3 and ~2.8 x 10^{-3} \text{cm}^3 observed in the samples which were plasma nitrided at 350 °C. The volume loss was found to increase with increasing nitriding temperature. It was also revealed that, at 450 °C volume loss exceeded in nitrided samples as compared to untreated samples for both the alloys.

Using the values of volume loss, calculated wear rate was calculated by using the following relation given in equation (4)

\[
\text{Wear rate} = \frac{\text{Volume loss}}{\text{(Sliding distance x Load)}} \tag{4}
\]

For the fixed value of the sliding distance (2000m), values of wear rate (mm$^3$/Nm) obtained have been shown in figure 11.

![Figure 11: Wear rate (mm$^3$/Nm) of untreated and plasma nitrided samples of Inconel 600 and 601.](image)

The minimum wear rates ~1.06 x 10^{-4} \text{mm}^3/\text{Nm} and ~1.4 x 10^{-4} \text{mm}^3/\text{Nm} were found for the samples of Inconel 600 and 601 alloys which were nitrided at 350 °C respectively. The wear rate was found to increase with increasing nitriding temperature. At 450 °C the wear rate exceeded ~4.84 x 10^{-4} \text{mm}^3/\text{Nm} and ~4.19 x 10^{-4} \text{mm}^3/\text{Nm}. 

mm$^3$/Nm as compared to untreated samples ~4.13 x 10$^{-4}$ mm$^3$/Nm and ~2.83 x 10$^{-4}$ mm$^3$/Nm for both the alloys. It is also observed that the increase of wear rate is fast in the Inconel 601 alloy as compared to Inconel 600 alloy. It may be related to the formation of a thin hard phase (CrN) at the surface of the Inconel 601 alloy at this particular temperature (450 °C). The thin hard CrN phase has the brittle nature that increases the wear rate. Kahraman et al. [37] reported that the samples which were nitrided for 10 h duration show maximum wear resistance due to the formation of thick compound and diffusion layer as compared to the samples which have a thin compound layer.

![Figure 12: SEM image of untreated and plasma nitrided samples of Inconel 600 alloy after wear test.](image)

![Figure 13: SEM image of untreated and plasma nitrided samples of Inconel 601 alloy after wear test.](image)

5. CONCLUSIONS

Based on this study following conclusions can be drawn:

(i) Plasma nitriding of Inconel 600 and 601 alloys at a temperature between 350 to 450 °C can produce a thin nitrided layer ~3.15 µm and ~3.70 µm. The thickness of the nitrided layer increases as nitriding temperature increases.
(ii) Surface microhardness was found to increase after plasma nitriding. It increases slowly up to 400 °C. The maximum surface micro-hardness ~306 HV,0.025 and ~330 HV,0.025 were observed at 450 °C in Inconel 600 and 601 alloys respectively.

(iii) CrN Phase was not detected in Inconel 600 alloy for all temperature range (350 – 450 °C). However, CrN Phase was detected in Inconel 601 samples that were plasma nitrided at 450 °C only. A mix peak of the epsilon (ε) phase with the γ phase of (111) and (200) planes were observed in all the nitrided samples for all temperature range 350 to 450 °C.

(iv) The values of diffusion coefficients ~9.5x10⁻¹⁶ m²/s and ~6.8x10⁻¹⁶ m²/s and the values of activation energy for the diffusion of nitrogen ~1.21 eV and ~1.24 eV were obtained for Inconel 600 and 601 alloys respectively. The whole process was seemed thermally activated and the growth of the nitrided layer was controlled by the diffusion of the nitrogen atom.

(v) The volume loss and wear rate were found to decrease after the plasma nitriding process. The minimum wear rate ~1.06 x 10⁻⁴ mm³/Nm and ~1.4 x 10⁻⁴ mm³/Nm were found in the samples of Inconel 600 and 601 alloys, which were nitrided at 350 °C. The SEM images agreed with the trends of our calculated values of wear rate with some anomaly.
